PROJECT PROPOSAL / OCTOBER 18, 2026

Local AI Field Notes

Practical, reproducible AI testing for people building with the computers they already have.

THE ASK

A modest GPU-credit grant or a returnable local-AI review system, scoped to a useful public test project.

Why this project

A model download count cannot tell a beginner whether a model will fit, respond quickly or follow instructions on their own machine. I am preparing a practical testing series that publishes the prompts, settings, results and limitations behind each demonstration.

A small, clear first release

- Reproducible tests. Summarization, structured extraction and English/Urdu assistance, with explicit task checks and human-review notes.
- Inspectable evidence. A versioned configuration for every run, raw outputs, timing records and a readable report. Failed runs remain visible.
- Useful explanations. Three short educational demonstrations showing setup, observed behavior and practical tradeoffs. No existing audience is claimed.

Starting point

Houston-based independent learner with a BBA in Marketing from Texas Southern University. Existing equipment includes a 32 GB M1 Max MacBook and a GTX 1080 Ti desktop with approximately 32 GB RAM. The project is early-stage; this brief does not claim measured performance or a launched channel.

TEST PLAN & SUPPORT SCOPE

Make every comparison inspectable.

Measurement protocol

- Record the configuration. Model identifier and digest, license reference, quantization, runtime version, hardware, context limit and generation settings.
- Separate kinds of timing. Distinguish cold/warm runs, load time, time to first token when measurable, generation throughput and total elapsed time. Document which metrics each runtime exposes.
- Keep comparisons honest. Use the same task set and disclose differences in model build, precision and runtime. Do not label unlike setups as controlled hardware-only comparisons.
- Check usefulness as well as speed. Validate extraction against known fields, preserve summarization constraints and use a transparent human rubric for language quality. Publish errors and uncertainty.

Proposed four-week delivery

- Week 1 - establish a baseline. Prepare the public repository, task cases and versioned configuration; record initial local runs.
- Week 2 - use granted access. Run bounded GPU experiments on available approved hardware and retain raw evidence.
- Week 3 - explain the results. Produce three concise walkthroughs and an accessible results report.
- Week 4 - make it reusable. Publish corrections, document setup friction and package reproduction instructions.

Budget discipline & editorial independence

The initial cloud request is USD 500, limited to granted credits. Run one instance at a time, stop idle resources and choose capacity around the model's memory requirement. Any review loan needs agreed return shipping, evaluation dates and responsibility terms before dispatch. Support will be disclosed; findings and limitations will be reported honestly.

Status: proposal and preparation. Deliverables above are planned, not claimed complete.
AI-assisted preparation is used; no unperformed benchmarks, subscriber counts or endorsements are represented as existing work.
